

Algorithms for reasoning over kinematic (geometric) and dynamic constraints

Planning as Search

- Discretize a continuous state space through random sampling → find shortest path over search tree → apply time-parameterization [1]
- Sample random configurations → connect with steering function [8]
- Sample random state and action → apply forward propagation [9]

[12, 15, 16]

- Generate task-biased state space samples
- ML model to verify trajectory feasibility [13]
- Learning-based dynamics for steering [14]

[3]

- Next-token (autoregressive) approaches: train a model to predict the next likely configuration [6]
- Full-sequence models: train a neural network to model distribution of trajectory space → infer solution for any new start/goal pair and environment [7] [10, 17]

Planning as Optimization

- Setup equality/inequality constraints → start with linear interpolation seed → warp for constraint satisfaction [2]

- Use a neural network to generate an informed seed for trajectory optimization [10]
- Model a dynamics constraint using machine learning [3]
